

Equivalent Fractions Lesson – 2

Now you have got the concept of equivalent fractions in the previous lesson. In this lesson we will learn a method to find [equivalent fractions](#) to a given fraction, using multiplication.

We will consider two thirds ($\frac{2}{3}$) as an example to explain it further as shown below:

All of the above fractions look different but represent the equal areas of the largest rectangle; hence all of the above fractions are equivalent to each other.

Let's rewrite the above fractions again and accomplish something:

$$\begin{array}{ccccccc} \frac{2}{3} & \xrightarrow{\times 2} & \frac{4}{6} & \xrightarrow{\times 2} & \frac{8}{12} & \xrightarrow{\times 2} & \frac{16}{24} \\ \frac{2}{3} & \xrightarrow{\times 2} & \frac{4}{6} & \xrightarrow{\times 2} & \frac{12}{12} & \xrightarrow{\times 2} & \frac{24}{24} \end{array}$$

Now, see how did we obtain $\frac{4}{6}$ from $\frac{2}{3}$; simple, isn't it? By multiplying numerator and denominator by 2. Similarly, we obtained $\frac{8}{12}$ from $\frac{4}{6}$ and $\frac{16}{24}$ from $\frac{8}{12}$.

Hence, to get an equivalent fraction to a given fraction, multiply the numerator and denominator of the given fraction by 2.

Is it only 2, can we multiply the numerator and denominator of a given fraction, to find its equivalent fraction?

No, 2 being the easiest is used only as an example. You can multiply the numerator and denominator of a given fraction by any number to get an equivalent fraction to a given fraction.

But remember the rule that multiply the numerator and denominator by the same number. If you multiply the numerator by 2 and denominator by 3, the fraction you get will not be the equivalent fraction to the original fraction.
